DEPARTMENT OF COMPUTER & INFORMATION SCIENCES

ABSTRACT

The Hospital Management System (HMS) is a comprehensive, role-based web application designed to streamline administrative, clinical, and operational processes within a healthcare facility. Developed using ASP.NET Web Forms (VB.NET) with a SQL Server backend, the system ensures efficient management of core hospital functions such as patient records, doctor scheduling, room assignments, tests, admissions, and billing operations.

This project specifically highlights the Doctor Dashboard module, which serves as a personalized interface for medical professionals within the system. Upon secure login, authenticated doctors can access a real-time overview of their upcoming and past appointments, including relevant details such as patient names, scheduled times, room numbers, and appointment statuses. Data is dynamically retrieved from a normalized relational database schema using role-specific queries, ensuring data privacy and access control.

By integrating the Doctor Dashboard, the HMS enhances physician productivity, reduces administrative overhead, and promotes patient-centric care. The modular design ensures scalability, allowing seamless extension to include additional features such as test result access, patient history summaries, and feedback integration in future iterations.

1. INTRODUCTION

The modern healthcare environment demands a high degree of coordination, transparency, and efficiency to meet the growing needs of patients and healthcare providers. Traditional paper-based systems are not only inefficient but also prone to errors, delays, and data redundancy. To address these challenges, digital healthcare systems have emerged as a robust solution for streamlining hospital operations and improving service delivery.

The Hospital Management System (HMS) is a web-based application designed to digitize the management of hospital activities including patient registration, appointment scheduling, staff allocation, room management, billing, and reporting. Built using ASP.NET Web Forms (VB.NET) with a SQL Server backend, the system ensures role-based access, data integrity, and operational efficiency across multiple departments.

One of the essential components of this system is the Doctor Dashboard, which provides physicians with a centralized interface to view and manage their appointments. This module enables doctors to stay informed about their daily schedules, patient assignments, and consultation logistics, thereby enhancing clinical workflow and patient satisfaction.

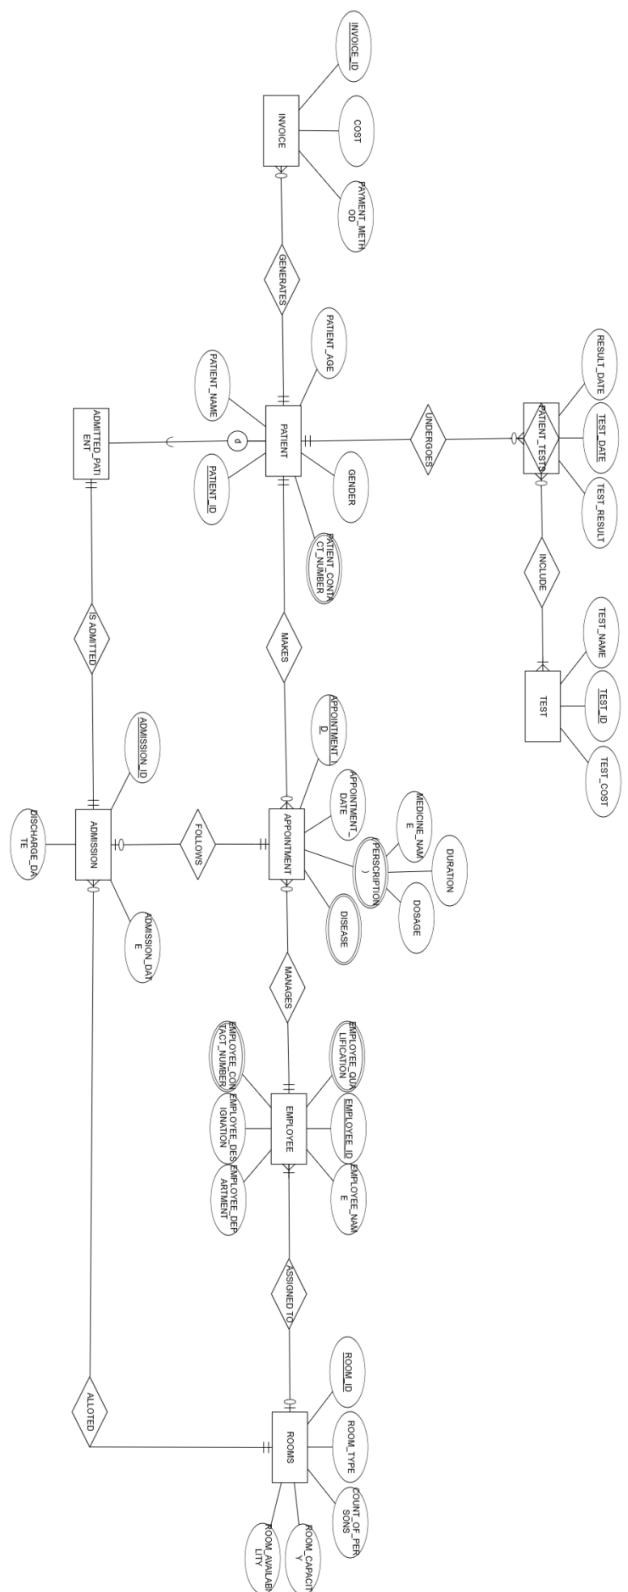

1.1 PROBLEM STATEMENT

Many hospitals still rely on manual processes for managing doctor schedules and patient appointments, leading to delays, miscommunication, and inefficiencies. Doctors often lack real-time access to their appointments, which hampers their ability to deliver timely and organized care. There is a need for a centralized digital system that enables doctors to efficiently manage and view their appointments with up-to-date information.

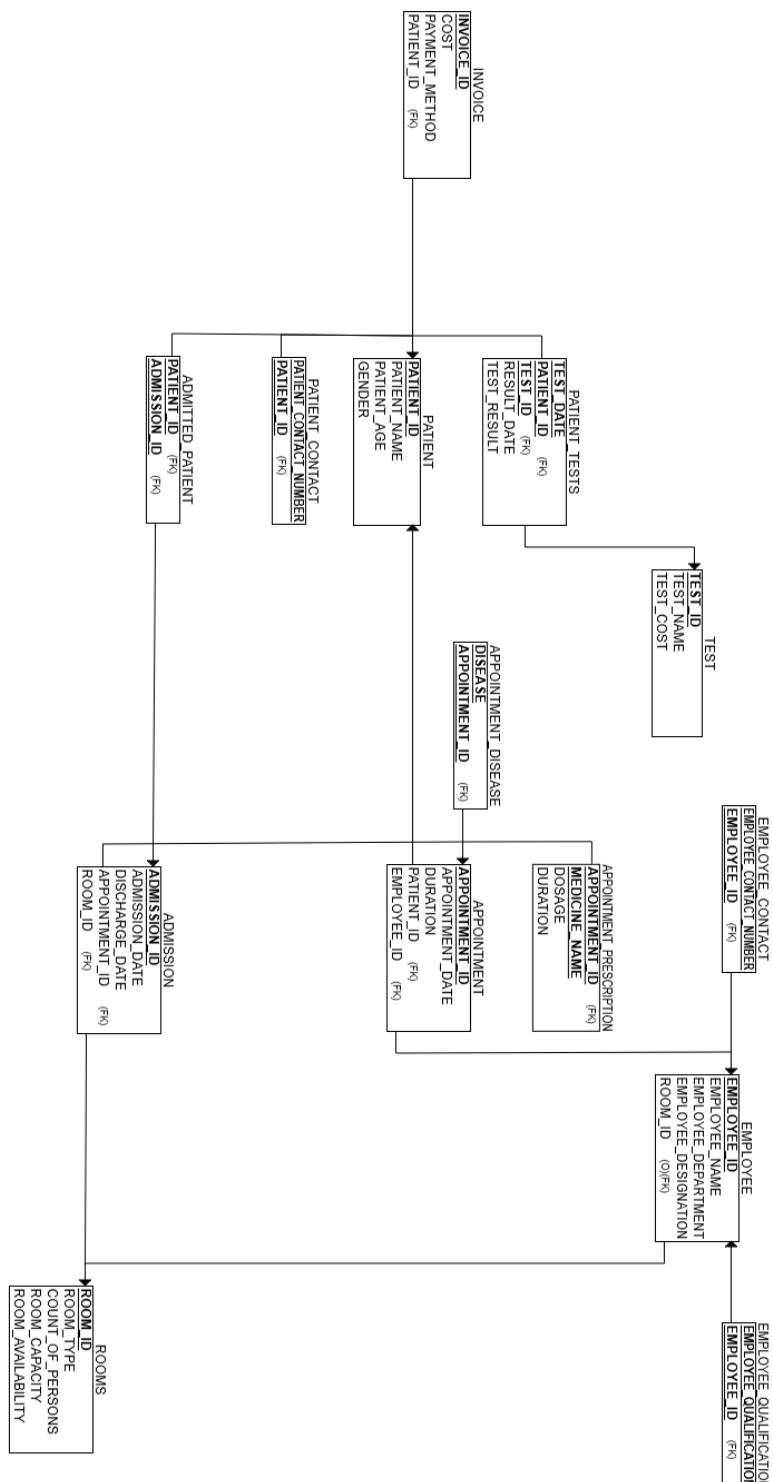

1.2 PROJECT SCOPE

This project focuses on developing a web-based Hospital Management System (HMS) with a key feature: the Doctor Dashboard. Using ASP.NET Web Forms and SQL Server, the system allows authenticated doctors to view their personalized appointment data, including patient details, timing, room assignments, and statuses. The system is designed to be secure, role-based, and scalable for future enhancements like test tracking and digital prescriptions.

2. COMPLETE ENTITY RELATIONSHIP DIAGRAM

3. RELATIONAL MODEL

4. NORMALIZATION

In this project, the database design adheres to the principles of **Third Normal Form (3NF)**. As all entities and relationships have been structured to comply with 3NF, further normalization is not required. Each table is free of partial and transitive dependencies, ensuring that:

1. All attributes depend solely on the **primary key** (no partial dependency).
2. There are no transitive dependencies where non-prime attributes depend on other non-prime attributes.

By achieving 3NF, the schema ensures minimal redundancy, improved data integrity, and optimal design for efficient querying and maintenance.
